INTRODUCTION

Diabetes mellitus affects more than 300 million individuals worldwide, with increasing prevalence particularly in the developing countries (Whiting et al., 2011). In fact, the prevalence of type 2 diabetes mellitus (T2DM) in China is among the highest in the world. The combination of insulin resistance in peripheral tissues and impaired insulin secretion from pancreatic β-cells is believed to contribute to the development and progression of T2DM. Both, the genetic and environmental factors confer susceptibility to T2DM. In recent years, studies of gene polymorphisms have helped identify a number of T2DM-susceptibility genes.

Gas6/Tam has a number of diverse functions, including the regulation of cell survival and proliferation, cell adhesion and migration, and others (Godowski et al., 2003). In recent years, several studies have explored the relationship between Gas6 polymorphisms and T2DM. Chien-Hsing Lee in Taiwan found that the Gas6 gene single nucleotide polymorphism (SNP) rs8191974 was associated with T2DM in the local population (Lee et al., 2012).

The adapter-related protein complex 3 subunit sigma-2 (Ap3s2) is located on human chromosome 13q34. Plasma Gas6 is a vitamin K-dependent protein very similar to plasma anticoagulant protein S and is comprised of the Gla domain (γ-carboxylated glutamic-acid-rich region) and four EGF-like domains (Bellido-Martin et al., 2008). Gas6 protein interacts with receptor tyrosine kinases of the Tyro-3, Axl, Mer (TAM) family (Hafizi et al., 2006). The Gas6/TAM system has a number of diverse functions, including the regulation of cell survival and proliferation, cell adhesion and migration, and others (Godowski et al., 1998; Nagata et al., 1996; Bellosta et al., 1997; Collett et al., 2003). In recent years, several studies have explored the relationship between Gas6 polymorphisms and T2DM. Ap3s2 gene SNP rs2028299 as a susceptibility locus for T2DM (GWAS) in people of South Asian ancestry identified 227–231.

Previous studies in other countries have shown that single nucleotide polymorphisms (SNPs) in the growth arrest-specific gene 6 (Gas6; rs8191974) and adapter-related protein complex 3 subunit sigma-2 (Ap3s2; rs2028299) were associated with an increased risk for type 2 diabetes mellitus (T2DM). However, the association of these loci with T2DM has not been examined in Chinese populations. We performed a replication study to investigate the association of these susceptibility loci with T2DM in the Chinese population. We genotyped 1968 Chinese participants (996 with T2DM and 972 controls) for rs8191974 in Gas6 and rs2028299 near Ap3s2, and examined their association with T2DM using a logistic regression analysis. We also analyzed the correlation of genotypes and clinical phenotypes. The distribution of T allele of SNP rs8191974 in the Gas6 gene was significantly different between T2DM cases and controls when compared with the C allele (P<0.05, OR: 0.80, 95% CI: 0.69–0.94). The occurrence of the CT genotype and the dominant model was also significantly less frequent in the T2DM cases vs. controls when compared with the CC genotype (CT vs. CC: P<0.05, OR: 0.75, 95% CI:0.62–0.90; TT+CT vs. CC: P<0.05, OR:0.75, 95% CI:0.63–0.90). In SNP rs2028299, the allele C showed no statistically significant difference in distribution between the control and T2DM groups when compared with allele A. However, in male populations, the dominant model was statistically more frequent when compared with genotype AA (CC+CA vs. AA: P<0.05, OR:1.29, 95% CI:1.02–1.64), and in obesity-stratified analysis, we also observed a significant difference in the distribution of the dominant model between the T2DM cases and controls in subjects with BMI≥24 kg/m² and BMI<28 kg/m² (CC+CA vs. AA: P<0.05, OR: 6.33, 95% CI:4.17–9.61). In conclusion, our study shows that SNP rs8191974 in the Gas6 gene was significantly associated with T2DM cases and controls in subjects with BMI≥24 kg/m², while SNP rs2028299 near Ap3s2 was related to T2DM in the Chinese population.

RESULTS

Subject Characteristics

There were four cases in the T2DM group and 28 cases in the control group without genotypes, so the final study included 996 T2DM patients and 972 control subjects.

Characteristics of the subjects are shown in Table 1. A slightly higher proportion of older subjects were observed among T2DM patients compared to controls, which may be due to a participation bias.

Table 4. Gender stratification analysis of Ap3s2 rs2028299 alleles/genotypes with T2DM.

**Correlation analysis of SNP rs8191974 and rs2028299 with T2DM**

As displayed in Table 2, rs8191974 showed an allelic difference between cases and controls in the Chinese population, with an OR of 0.80 (95% CI:0.69–0.94, P<0.004); however, SNP rs2028299 showed no significant difference between the A and C alleles in the two groups.

We further analyzed the effect of the genotypes of the two SNPs under a dominant genetic model by logistic tests (Table 3). The CT genotype and the dominant model displayed significant differences between cases and controls when compared with the CC genotype (CT vs. CC: P<0.05, OR:0.75, 95% CI:0.62–0.90; TT+CT vs. CC: P<0.05, OR:0.75, 95% CI:0.63–0.90).

In the male populations, the dominant model was significantly different when compared with the AA genotype (CC +CA vs. AA: P<0.05, OR:1.29, 95% CI:1.02–1.64; Table 4). In the female subjects, there were no differences in any genotype between the two groups (Table 4).

**DISCUSSION**

To date, more than 120 genetic loci have been suggested to be associated with T2DM, or with glucose and insulin levels in the European and multi-ethnic populations (Sladek et al., 2007; Zeggini et al., 2008; Dupuis et al., 2010; Imamura et al., 2011; Lyssenko et al., 2015). Of these, several loci have been shown to be associated with T2DM in different ethnic groups, whereas the remaining loci have not shown any significant effects in the ethnic populations other than those in the original reports. Although the power of these studies may be insufficient in some cases, genetic heterogeneity among different ethnicities may exist for some particular loci. In this study, we examined the association of SNP rs8191974 and rs2028299 with susceptibility to T2DM in a Chinese population and showed that they were significantly associated.

Previous studies indicated that the Gas6/TAM system was involved in the pathogenic mechanism for renal and cardiovascular complications associated with diabetes (Nagai et al., 2003; Cavet et al., 2008). Recent studies in animal models have shown that Gas6/TAM signaling plays an important role in pathophysiological mechanisms underlying obesity-related inflammation and insulin resistance (IR) (Augustine et al., 1999). Hsieh et al., had suggested that the Gas6 gene variants were associated with IR, although their effects on subsequent progression to T2DM were minimal in this study (Augustine et al., 1999). Hsieh et al., 2015). It is also important to mention that the Gas6 polymorphism has been associated with stroke (Muñoz et al., 2004; Muñoz et al., 2007). The Hsieh study conducted in Taiwan had shown that the Gas6 gene rs8191974 mutations reduced the risk of T2DM (Lee et al., 2012). Likewise, our study found that the SNP rs8191974 T allele is a protective factor in T2DM, consistent with the Taiwanese study (Lee et al., 2012). Northern and southern Chinese have obviously different living environments and lifestyles. However,
that SNP rs8191974 is associated with an increased risk of T2DM via these indicators. In recent years, increasing attention has been paid to the role of fatty acid toxicity in the pathogenesis of T2DM. We hypothesize that rs8191974 is likely to affect the risk of T2DM factors involving obesity and lipid metabolism in the pathogenesis of T2DM. This theory will require subsequent experimental verification.

The Ap3s2 protein is widely distributed in the islet and fat cells. A South Asian GWAS had shown that the Ap3s2 gene SNPsrs2028299 had relatively strong links to T2DM (Kooner et al., 2011). In addition, the association of rs2028299 and T2DM was examined in a Japanese population in which it was shown that the genetic risk score was significantly associated with T2DM (Fukuda et al., 2012). Our study found that SNP rs2028299 allele C and dominant model CC + CA vs. AA were risk factors for T2DM in males, but we observed no association between SNP rs2028299 and T2DM in females. It may be that subject variation among male and female participants or differing levels of sex hormones caused false negative results.

In a subsequent analysis to determine the association of SNP rs2028299 with weight, we found that subjects with the CA genotype had greater weight among all T2DM patients. It has been previously reported that SNP rs2028299 was associated with increased patient BMI levels (Fukuda et al., 2012), and studies have confirmed that excess weight or BMI can cause insulin resistance. Combining the results of our study and related literature reports (Kooner et al., 2011; Fukuda et al., 2012; van de Bunt et al., 2013), we suggest that SNP rs2028299 may participate in the occurrence and development of T2DM in one of the following ways: 1) Disturbing the intracellular localization of the insulin receptor substrate to affect insulin function; 2) Altering the expression of microRNAs in islet cells to affect the secretion of insulin; 3) Since SNP rs2028299 is widely expressed in fat cells, its mutations may increase the BMI of T2DM patients, which can lower insulin sensitivity and indirectly cause insulin resistance; 4) SNP rs2028299 may affect nearby loci that are correlated with T2DM and thus indirectly influence the occurrence and development of T2DM.

CONCLUSION

We have observed a significant association of Gas6 rs8191974 and Ap3s2 rs2028299 with type 2 diabetes in a Chinese population. Our results suggest that both SNPs are common T2DM susceptibility loci in differ-

the fact that both, our study and Lee et al. found that SNP rs8191974 was associated with T2DM, suggests that the contribution of genetic factors is greater than environmental factors in Chinese T2DM.

The molecular mechanisms by which the Gas6 gene participates in T2DM have not yet been elucidated. Lee et al. speculated that the Gas6 gene polymorphisms participated in the occurrence and development of T2DM by altering the function of the islet cells (Lee et al., 2012). Among the T2DM group, we found that subjects with the rs8191974 CC genotype had higher glucose, weight, waistline and hipline values. It is well known that the three indicators of weight, waistline and hipline are commonly used measures of obesity, so it may be the case
ent ethnic groups. However, further functional studies will be required to elucidate the biological mechanisms underlying each locus which confer susceptibility to the disease.
